

LES SÉANCES DE LA SOCIÉTÉ PRÉHISTORIQUE FRANÇAISE

Les Séances de la Société préhistorique française sont organisées deux à trois fois par an. D'une durée d'une ou deux journées, elles portent sur des thèmes variés : bilans régionaux ou nationaux sur les découvertes et travaux récents ou synthèses sur une problématique en cours dans un secteur de recherche ou une période en particulier.

La Société préhistorique française considère qu'il est de l'intérêt général de permettre un large accès aux articles et ouvrages scientifiques sans en compromettre la qualité ni la liberté académique. La SPF est une association à but non lucratif régie par la loi de 1901 et reconnue d'utilité publique, dont l'un des buts, définis dans ses statuts, est de faciliter la publication des travaux de ses membres. Elle ne cherche pas le profit par une activité commerciale mais doit recevoir une rémunération pour compenser ses coûts de gestion et les coûts de fabrication et de diffusion de ses publications.

Conformément à ces principes, la Société préhistorique française a décidé de proposer les actes des Séances en téléchargement gratuit sous forme de fichiers au format PDF interactif. Bien qu'en libre accès, ces publications disposent d'un ISBN et font l'objet d'une évaluation scientifique au même titre que nos publications papier périodiques et non périodiques. Par ailleurs, même en ligne, ces publications ont un coût (secrétariat d'édition, mise en page, mise en ligne, gestion du site internet) : vous pouvez aider la SPF à poursuivre ces activités de diffusion scientifique en adhérent à l'association et en vous abonnant au *Bulletin de la Société préhistorique française* (voir au dos ou sur <http://www.prehistoire.org/form/515/736/formulaire-adhesion-et-ou-abonnement-spf-2014.html>).

LA SOCIÉTÉ PRÉHISTORIQUE FRANÇAISE

La Société préhistorique française, fondée en 1904, est une des plus anciennes sociétés d'archéologie. Reconnue d'utilité publique en 1910, elle a obtenu le grand prix de l'Archéologie en 1982. Elle compte actuellement plus de mille membres, et près de cinq cents bibliothèques, universités ou associations sont, en France et dans le monde, abonnées au *Bulletin de la Société préhistorique française*.

Tous les membres de la Société préhistorique française peuvent participer :

- aux séances scientifiques de la Société – Plusieurs séances ont lieu chaque année, en France ou dans les pays limitrophes. Le programme annuel est annoncé dans le premier *Bulletin* et rappelé régulièrement. Ces réunions portent sur des thèmes variés : bilans régionaux ou nationaux sur les découvertes et travaux récents ou synthèses sur une problématique en cours dans un secteur de recherche ou une période en particulier ;
- aux Congrès préhistoriques de France – Ils se déroulent régulièrement depuis la création de la Société, actuellement tous les quatre ans environ. Leurs actes sont publiés par la Société préhistorique française. Depuis 1984, les congrès se tiennent sur des thèmes particuliers ;
- à l'Assemblée générale annuelle – L'Assemblée générale se réunit en début d'année, en région parisienne, et s'accompagne toujours d'une réunion scientifique. Elle permet au conseil d'administration de rendre compte de la gestion de la Société devant ses membres et à ceux-ci de l'interpeller directement. Le renouvellement partiel du conseil se fait à cette occasion.

Les membres de la Société préhistorique française bénéficient :

- d'information et de documentation scientifiques – Le *Bulletin de la Société préhistorique française* comprend, en quatre livraisons de 200 pages chacune environ, des articles, des comptes rendus, une rubrique d'actualités scientifiques et une autre sur la vie de la Société. La diffusion du bulletin se fait par abonnement annuel. Les autres publications de la SPF – Mémoires, Travaux, Séances, fascicules des Typologies de la Commission du Bronze, Actes des Congrès, Tables et index bibliographiques ainsi que les anciens numéros du *Bulletin* – sont disponibles au siège de la Société préhistorique française, sur son site web (avec une réduction de 20 % pour les membres de la SPF et téléchargement gratuit au format PDF lorsque l'ouvrage est épousé) ou en librairie.
- de services – Les membres de la SPF ont accès à la riche bibliothèque de la Société, mise en dépôt à la bibliothèque du musée de l'Homme à Paris.

Régie par la loi de 1901, sans but lucratif, la Société préhistorique française vit des cotisations versées par ses adhérents. Contribuez à la vie de notre Société par vos cotisations, par des dons et en suscitant de nouvelles adhésions autour de vous.

ADHÉSION ET ABONNEMENT 2017

Le réabonnement est reconduit automatiquement d'année en année*.

Munzingen

A Magdalenian site in the Southern Upper Rhine plain (Germany)

Clemens PASDA

Abstract: During 1914–15 a large Magdalenian site was excavated at Munzingen (County Breisgau-Hochschwarzwald, Germany). In the light of recent results on the early part of the Magdalenian of France, the presence of reindeer antler points at Munzingen might well indicate the presence of a Lower Magdalenian that dates to approximately 20–18 ka cal. BP. This interpretation is supported by five of the nine reliable radiocarbon dates, the presence of woolly rhinoceros and the loess cover. Characteristic lithic artefacts may support this interpretation as well, but as so often, there remain some doubts.

Keywords: Magdalenian, Lower Magdalenian, Middle Magdalenian, open-air site, excavation in 1914–15, loess, chronostratigraphy, typology.

Résumé : Entre 1914 et 1915, un grand site magdalénien a été fouillé à Munzingen (arrondissement de Breisgau-Hochschwarzwald, Allemagne). D'après les résultats des recherches actuelles sur le Magdalénien en France, les sagaies de Munzingen semblent indiquer la présence d'un Magdalénien inférieur (*ca* 20–18 ka cal. BP). Cinq des neuf dates ¹⁴C sûres, la présence du rhinocéros laineux et la couverture loessique conforteraient cette interprétation. Les outils lithiques peuvent également la supporter, mais leur discussion n'est pas sans contradiction.

Mots-clés : Magdalénien, Magdalénien inférieur, Magdalénien moyen, site de plein-air, fouilles en 1914 et 1915, lœss, chronostratigraphie, typologie.

The stones found in nature, like facts,
are endlessly numerous, wild and complex.

Bernd Heinrich in *The homing instinct* (Boston, 2014, p. 16).

IN 1874 the first Magdalenian artefacts have been found in loess deposits approximately 600 m southwest of the village of Munzingen near Freiburg im Breisgau (fig. 1). Artefacts occurred on an area of some 25,000 m² (Kind, 2008) but, unfortunately, the loess deposits had been disturbed due to several factors like erosion since prehistoric times, Neolithic settlement, medieval quarrying and well construction, wine-growing, road construction and the creation of two modern sports arenas. However, during his excavation of 1914–15, August Padtberg, then a student at the University of Freiburg im Breisgau,⁽¹⁾ collected around 20,000 stone artefacts, thousands of rocks and many faunal remains on a surface area of about 200 m² (table 1).

STRATIGRAPHY, ROCKS AND HEARTHS, FAUNA, ENVIRONMENT AND HUNTING, LITHIC RAW MATERIAL AND MOLLUSKS

According to Padtberg's observations, the artefacts occurred in a dark and red to brownish, humic horizon that was covered by silty sediments of 0.8 to 2.3 m thickness (fig. 1). The results of this large excavation were published in 1925 and Munzingen was assigned to an 'Early Magdalenian' (Padtberg, 1925, p. 69). Today, beside some rocks, only ca. 4,200 lithic artefacts, ca. 160 organic artefacts and ca. 260 faunal remains have survived of the excavated material. Because the excavation was performed without sieving of the sediment, small lithics (< 1 cm), backed bladelets and burin spalls are underrepresented. Nevertheless, the reinvestigation of

1914–15	A. Padtberg	Large excavation (30 × 10 m)	ca. 20,000	+	Large Magdalenian site
1933–44	G. Kraft	Several excavations	single	–	Late Holocene context
1960	E. W. Guenther, L. F. Zotz	Stratigraphy	few	+	
1976–77	G. Albrecht	Salvage excavation (6–7 m ²)	ca. 1,500	–	In loess
2007	C.-J. Kind	Salvage excavation	some	–	In loess

Note: AH = archaeological horizon as defined by Padtberg (1925, p. 24), + present, – not present.

Table 1 – Excavations at Munzingen.
Tabl. 1 – Fouilles à Munzingen.

these finds resulted in a reconstruction of Magdalenian life in the late Würmian Upper Rhine plain (Pasda, 1994). Many rocks from local outcrops nearby have been imported to be used in a typical Magdalenian fashion where repetitive use of stone-covered fires (Leesch,

1997, p. 170–175; Plumettaz, 2007) resulted in a ‘pavement-like’ (Padtberg, 1925, p. 49) distribution of rocks. At least six hearths may have been present where bones and willow have been burnt. Remains of reindeer dominate the faunal assemblage whereas bones of horse,

woolly rhinoceros, mountain hare, wolverine and red fox constitute just 10% of all identified specimens. These animal species may indicate the local environment during GS-2.1b/GS-2.1a (table 2) as a grassland with alpine and steppe herbs and maybe some dwarf shrub (Leesch et al., 2012b), with high seasonality, a mean July temperature of around 9°C and very cold winters (Lotter et al., 2012, p. 109). Due to dentition of reindeer, a warm season occupation seems the most likely. The hunting area may have been not that far away as presence of all skeletal parts from reindeer, horse and rhinoceros indicate. Munzingen is situated at a topographical bottleneck, where the loess-covered hills narrow to end between large fluvial plains (fig. 1). Therefore, the site may be ideal to intercept migrating herds, an interpretation which may be also supported by the presence of both juvenile and adult individuals of reindeer, horse and rhinoceros.

Around 57 kg of lithic artefacts were excavated by Padtberg (1925, p. 54). This does not indicate a prolonged stay at the site as, in comparison, on the 400 m² of the Magdalenian site of Monruz, which was in use during a rather short period of time, ca. 77 kg lithic artefacts were recovered (Cattin, 2012, fig. 14). The lithic raw material pattern in Munzingen does not differ from younger Magdalenian sites nearby (Pasda, 1998b, fig. 28d): the best lithic raw material, a white or brown-red Jurassic hornstone was used most often (63%), despite being only available ca. 20–40 km away in the foothills of the most southern part of the Upper Rhine plain (Kaiser, 2013). A wide variety of lithic materials from regional (<20 km) outcrops were also used, among which Triassic shelly hornstone predominates (23%). Exotic lithic raw material is apparently not present, yet some lithics were possibly imported from a distance of up to 50 km, but here are more detailed studies necessary. A connection with regions far away

is indicated by the presence of four mollusk shells. Two pierced *Cyrena semistriata* were imported from the Basin of Mayence, which is situated ca. 200 km to the north and a single pierced *Nucella lapillus* was imported from the Atlantic coast, situated > 500 km far away. In addition, in a salvage excavation in 1976–77 (table 1), a single *Homalopoma sanguineum* was found, which has been imported from the Mediterranean Sea, maybe from the mouth of the river Rhône, more than 500 km away (Alvarez Fernández, 2001 and 2002). All mollusk species present at Munzingen have been very rarely used in other Magdalenian sites in South Germany and Switzerland (Pasda, 1998b, table 50).

Chronology: the ¹⁴C dates

After Worldwar II, the age of Munzingen has been rarely discussed (e.g. Sonnevile-Bordes, 1968) and recent salvage excavations by the Landesdenkmalamt Baden-Württemberg did not rediscover the archaeological horizon described by A. Padtberg (table 1). However, the interpretation as ‘Early Magdalenian’ was reinforced when the first ¹⁴C date became available (Hahn, 1981a and 1981b). In the 1990s, many more ¹⁴C dates were obtained but their wide range, from the late Würmian well into the early Holocene (table 2), led to the interpretation that “Munzingen (...) is a Magdalenian site of unknown age” (Housley et al., 1997, p. 32). However, this reading was not accepted by German archaeologists (e.g. Kind, 2003; Street et al., 2012) since radiocarbon dating of bones from old excavations regularly yields aberrant dates (Leesch and Müller, 2012a). For example, OxA-4789 (tabl. 2, no. 12) may indicate a Holocene reindeer, ca. 3,000 years after its disappearance in South France (Langlais et al., 2012, p. 142) and in the Jura mountains (Drucker et al., 2012).⁽²⁾

					XIV

Notes: H4156-3373 and H4738-4660 are ¹⁴C dates made on bulk samples of many single undetermined bone fragments, all other dates are made by accelerator mass spectrometry on single reindeer bones; calibration according to Reimer et al. (2009) with OxCal v3.10; Greenland ice core climatostratigraphy by Rasmussen et al. (2014); see figure 1 for areas as documented by Padtberg (1925, fig. 2).

Table 2 – List of ¹⁴C dates of Munzingen.

Tabl. 2 – Liste des dates ¹⁴C de Munzingen.

Also, OxA-4787 and H4738-4660 (tabl. 2, nos 10 and 11) are too young for the presence of woolly rhinoceros (Markova et al., 2013, p. 12; Stuart and Lister, 2012, p. 9) and too young to explain an aeolian accumulation of a > 80 cm thick loess cover (Antoine et al., 2009, p. 2968; Frechen et al., 2003) on top of the archaeological horizon (fig. 1). When taking into account the first nine dates (table 2), Munzingen is dated into the cold part of the Late Würmian (GS-2.1b/GS-2.1a). The first five dates, obtained by different laboratories, are very close to each other, between 19.5–18.5 ka cal. BP. Dates 6 and 7 indicate a younger time period of 17.8–17.2 ka cal. BP, which may be the start of ‘Heinrich event 1’, a time with a drop in temperature and increased aridity, but also with changes in the atmospheric radiocarbon content, resulting in a ^{14}C age plateau (Hemming, 2004; Reimer et al., 2009; Stanford et al., 2011). In contrast, the last two dates (table 2, nos. 8 and 9) indicate a third, even younger time period of 16.5–15.5 ka cal. BP.

It is impossible to show exactly which reason is responsible for presence of three different time periods (Pasda, 1998a). The archaeological investigation indicates a rather short human occupation at Munzingen since—like in well preserved Upper Magdalenian sites like Pincevent IV20 (Bodu, 1996; Enloe and David, 1992), Monruz (Cattin, 2012; Plumettaz, 2007) or Champréveyres (Cattin, 2002; Leesch, 1997)—refitting of stone artefacts (e.g. fig. 2, no. 12; fig. 3) and animal bones, as well as the spatial distribution of distinct lithic raw material units, demonstrate connections over the whole excavated area (Pasda, 1994). However, because of the focus in 1914–15 on the highly visible, dark and red horizon, it cannot be ruled out that faint horizons of flint and bone scatters in loess above or below this horizon were not recognized. When plotting the nine reliable radiometric dates on the excavation plan, three of the four younger (< 18.0 ka cal. BP) dates derive from the southern part of the excavation area (table 2, areas XIII and XIV). This might indicate the presence of one or two younger horizons in this zone. But this interpretation remains open to debate since chemical preservation of bones after excavation (Padtberg, 1925, p. 31) and/or contamination by infiltration with calcareous substances (Padtberg, 1925, p. 25) can also be responsible for measuring very different ^{14}C ages.

To sum up, radiometric data from Munzingen indicate an age in GS-2.1b/GS-2.1a with three sub stages of which the oldest and, by number of dates, the most pronounced level may be connected with the northern part of the excavation area. In the following section the discussion of lithic and organic artefact types will be used to give further information on the archaeostratigraphic position of Munzingen.

CHRONOLOGY: THE LITHICS AND ANTLER TOOLS

Of course, Munzingen does not show any relation to the Badegoulian since it is much younger than the

Badegoulian in Switzerland (Leesch et al., 2012b, p. 197) and Southern France (Ducasse, 2012). Moreover, lithics as well as organic artefacts differ from Badegoulian artefacts (Ducasse, 2012; Leesch and Bullinger, 2013; Pétillon and Ducasse, 2012) since, for example, the Magdalenian groove technique (Ducasse et al., 2011, p. 141; Langlais et al., 2010, p. 18–20) is well present at Munzingen by 70 antler cores and manufacture debris. Munzingen does not even show an ambiguous relation to the well-dated, 15.8–14.7 ka cal. BP old Upper Magdalenian sites of Monruz and Champréveyres in Switzerland—to which Teufelsküche, a small rockshelter site near to Munzingen (fig. 1), may be attributed—because no antler points with double beveled base, no obvious long borers, no Lacan-like burins and no small female figurines manufactured of jet are present (Leesch et al., 2012b). Additionally, rectangles, which may characterize a later phase of this Upper Magdalenian in Switzerland (Leesch et al., 2012b, p. 197), are not present among the lithics excavated at Munzingen in 1914–15, although one rectangle was found during the 1976–77 excavations (fig. 8, no. 15).

In general, Munzingen does not show a relation with Birseck-Ermitage and Kesslerloch in Switzerland (Leesch, 1997, p. 28–29; Leesch et al., 2012, p. 197 and 203) and with the 18–16 ka cal. BP old Middle Magdalenian in France (Angevin and Surmely, 2013; Langlais, 2007, p. 762; 2008; 2010, p. 127–129 and 2011, p. 719; Langlais et al., 2010 and 2012; Primault et al., 2007b, p. 751–755) since no triangle, no scalene bladelet, no microburin, no *navette*, no *baguette demi-ronde*, no Lussac-Angles antler point and no antler point with a single bevel is present. On the contrary, heavy retouch on blades, flakes and tools occurs at Munzingen (table 3; fig. 4, no. 12; fig. 5, nos. 1, 2 and 5) and at some Middle Magdalenian sites, like Canecaude (Langlais, 2010, p. 177) or Arlay (David, 1996, p. 171–172). However, concerning lithic artefacts, Munzingen (table 3) and Arlay (Cupillard and Welté, 2006; David, 1996, p. 169–176), which is situated only 200 km to the southwest, share some characteristics like the dominance of the burins over endscrapers and the occurrence of many backed bladelets and lateral retouched blades. However, at Arlay dihedral burins dominate among the different burin types and concerning organic artefacts, Arlay is characterized by *navettes* and antler points with grooves and double beveled bases, both often decorated, which are not present at Munzingen. At Munzingen, two thirds of the lateral retouched blades and flakes were recovered in the southern part of the excavated area, where most of the < 18 ka cal. BP dates were obtained. Whether this indicates a Middle Magdalenian occupation in this zone remains difficult to judge. However, it has to be emphasized that heavy lateral retouch is also present at Upper Magdalenian sites, for example at Champréveyres, where only some blades and end scrapers have a distinct lateral retouch (Cattin, 2002, pl. 13, nos. 7 and 11–13; pl. 14, no. 3; pl. 18, nos. 1 and 8–10; pl. 20, no. 21). Therefore, the attribution of Munzingen to the Middle Magdalenian is still a matter of debate.

As shown by recent research results on the 20.5–18.0 ka cal. BP old Lower Magdalenian in France (Ducasse et al., 2011, p. 141; Langlais, 2010, p. 127–129), with investigations on sites like Abri Gandil (Langlais et al., 2007), Petit-Cloup-Barrat (Ducasse et al., 2011), Scilles cave (Langlais et al., 2010) or Taillis-des-Coteaux (Primault et al., 2007a), blade and microblade production was important (Ducasse et al., 2011, p. 141). This is also the case at Munzingen, since blades and bladelets dominate among blank types (63%) and were selected for tool production. Because cores with negatives of flakes are rare (fig. 2, no. 2; fig. 3, no. 1), most often exploitation of cores stopped before exhaustion, when removal of blades was no more possible. To produce blades, large frost sherds (fig. 2, no. 5; fig. 3, no. 3) and large chunks (fig. 3, no. 4) were used. Some blade cores were used as bladelet cores in a later phase of the *chaîne opératoire* (fig. 2,

nos. 5, 10 and 12; fig. 3, no. 3), but primary production of bladelets was also performed on small frost sherds (fig. 2, nos. 2, 7 and 8), small nodules (fig. 2, nos. 6 and 9–11) or small blocks (fig. 2, no. 12). When the shape of the core was ideal, no preparation was done (fig. 2, no. 1; fig. 3, no. 1). Preparation is present on the foot (fig. 2, nos. 2, 8 and 12), on one flank (fig. 2, nos. 4 and 7), on one foot and on one side (fig. 2, no. 5) or on the back of the core (fig. 2, no. 6; fig. 3, no. 3).

Among the artefacts excavated in 1914–15, no microbladelets are present, which is probably due to non-sieving. However, cores and tool-like cores indicate that microbladelets were produced at Munzingen like in the French Lower Magdalenian (Bazile and Boccaccio, 2007, p. 792; Ducasse and Langlais, 2007, fig. 4; Ducasse et al., 2011, p. 120 et 141; Langlais et al., 2007, p. 354–357 and 2010, p. 15; Primault et al., 2007a, p. 19) from thick and long flakes (fig. 2, no. 3), from some cores looking like carinated scrapers (fig. 2, no. 1), from transversal and Corbiac burins (fig. 5, no. 7; fig. 6, no. 1) and from prismatic burins (fig. 6, no. 3).

As at other Magdalenian sites (Leesch 1997, p. 22 and 79), due to non-sieving at the 1914–15 excavations, the number of backed bladelets is low at Munzingen. However, like in the French Lower Magdalenian (Bazile et al., 1989, p. 72; Ducasse et al., 2011, p. 114; Langlais et al., 2007, p. 350; Primault et al., 2007a, p. 19), simple backed bladelets dominate at Munzingen, often of 3–4 cm in length and with a straight profile (fig. 4, nos. 5–7). Only few bilateral retouched bladelets occur (fig. 4, nos. 8, 14 and 16), with one side often not backed completely (fig. 4, nos. 9, 15 and 17–19). Some truncated backed pieces (fig. 4, no. 10) and single denticulated backed bladelets occur. Narrow backed pieces occur also but none has a pronounced pointed edge (fig. 4, nos. 14 and 17). Some backed bladelets are fragmented by impact fractures (fig. 4, no. 8). As mentioned above, bladelets for backing were detached from bladelet cores but manufacture debris (fig. 4, no. 7) indicates also the use of curved blades for modification of backed bladelets. However, it has to be emphasized that according to backed bladelets alone, Munzingen does not indicate a Lower Magdalenian: first, denticulated backed bladelets, backed bladelets with truncation, and pointed bladelets with bilateral backing also occur at the Upper Magdalenian sites Champréveyres (Cattin, 2002, pl. 1–4) and Monruz (Cattin, 2012, fig. 17). Second, the slender appearance of backed bladelets at Munzingen (fig. 4) may be misleading because their width is the same as in Champréveyres (Cattin, 2002, fig. 51). Also, both arguments do not allow the slender, bilateral backed bladelets with faint points of Munzingen (fig. 4, nos. 14, 16 and 19) to be identified as Epigravettian points (Bazile, 2011; Bazile and Boccaccio, 2007).

Another distinct type of the French Lower Magdalenian is a thin, asymmetric and twisted, 15–30 mm long bladelet with a natural point, a faint retouched, straight back on the right side and a sharp, convex edge on the left side that was produced from asymmetric and

convergent blanks (Bazile and Boccaccio, 2007, p. 792; Ducasse et al., 2011, p. 114–15 and 141; Langlais, 2011, p. 719; Langlais et al., 2007, p. 351 and 2010, p. 12–15). This type is not present among the tools excavated by Padtberg as no sieving was performed during the excavation in 1914–15. However, during the 1976–77 salvage excavation, many fragments of small backed bladelets (fig. 8, nos. 1, 5, 7–9, 12 and 14), some with an unmodified convex edge (fig. 8, nos. 2, 4 and 6), some with a retouch on the ventral side (fig. 8, nos. 3–4 and 10–11), have been found due to sieving. Beside this, during the 1976–77 excavations also tiny cores (fig. 8, no. 17), flakes used as cores (fig. 8, no. 16) and bladelet cores (fig. 8, no. 18) have been recovered but these lithics occur 10–20 m far away in loess and not in the distinct archaeological horizon of the 1914–15 excavations. Also, it has to be emphasized that at the Upper Magdalenian site Champréveyres comparable, tiny fragments of backed bladelets have been found due to sieving, some with retouch on the ventral face, others with alternating retouch, some with an unmodified, convex edge (Cattin, 2002, pl. 2–4). This prevents from taking the lithics of the 1976–77 excavations as pure evidence of the presence of a Lower Magdalenian at Munzingen.

Another distinct tool type of the Lower Magdalenian in France is the shouldered point (Langlais, 2010, p. 719), which occurs at Abri Gandil, c. 20 (Langlais et al., 2007, p. 347–350) and Fontgrasse (Bazile, 2006; Bazile and Boccaccio, 2007, p. 792). At Munzingen, fragments of four to five backed pieces have the shape of shouldered points (fig. 4, nos. 1–4). These artefacts were recognized by R. R. Schmidt (1912, p. 68) and Padtberg (1925, p. 61) already. However, in contrast to the shouldered points of Abri Gandil and Fontgrasse, where retouch is present on one side only, the base of the presumed shouldered points of Munzingen is situated on the ‘left’ side (fig. 4, nos. 1–4), whereas the tip is an oblique truncation on the ‘right’ side (fig. 4, nos. 2–3). Comparable points occur in another archaeostratigraphic context in the Salpêtrière cave in the Languedoc (Boccaccio, 2005, fig. 24, no. 5; fig. 28, nos. 3 and 5; fig. 30, nos. 4 and 12) and in the Paina cave near Venice in Italy (Broglia et al., 1993, fig. 4). Although these Munzingen artefacts have the shape of shouldered points they may represent only manufacture debris of backed bladelets (fig. 4, no. 2) or borers (fig. 4, no. 1) or are edge-damaged (fig. 4, nos. 3–4).

Just like at Munzingen, burins dominate at most Lower Magdalenian sites in France (Ducasse et al., 2011, p. 111; Langlais et al., 2010, p. 12). In contrast to Munzingen, burins and endscrapers occur in the same amount at Abri Gandil, c. 20, and Fontgrasse, the only sites with shouldered points (Bazile and Boccaccio, 2007, p. 792; Langlais et al., 2007, p. 347). Again in contrast to Munzingen, where burins on truncation (fig. 5, no. 4 and 6; fig. 6, no. 3) and dihedral burins occur in the same number, the dihedral burin is the most common burin type in the French Lower Magdalenian (Bazile

et al., 1989, p. 72; Ducasse et al., 2011, p. 111; Langlais et al., 2010, p. 12).

Finally, one of the main arguments that supports a Lower Magdalenian date of Munzingen is presented by the 67 reindeer antler points (fig. 7). Points with a round or elliptic cross-section and a simple or pointed base, often very long, up to 30 cm, characterize the 20–18 ka cal. BP old Lower Magdalenian in France (Ducasse et al., 2011, p. 133 et 141; Langlais, 2010, p. 274; Langlais et al., 2007, p. 358–359 and 2010, p. 23; Pétillon et al., 2011, p. 1268–1269). Unfortunately, preservation is not good at Munzingen, yet no antler point shows a bevel or a groove, all indicate long points with pointed, massive or simple bases and rectangular (fig. 7, nos. 3–6) as well as rounded cross-sections (fig. 7, nos. 1 and 2). Characteristic breaks (fig. 7, nos. 1, 2 and 5) are being interpreted as impact fractures (Stodiek, 1993, p. 169). Maybe ‘pseudo-baguette demi-rondes’ (Ducasse et al., 2011, p. 141; Langlais et al., 2010, p. 21) are present as well, but fragmentation and bad preservation make identification of this Lower Magdalenian type difficult.

Like in the French Lower Magdalenian (Ducasse et al., 2011, p. 138 et 141; Langlais et al., 2010, p. 28), and also in the Swiss Upper Magdalenian (Leesch, 1997, p. 95–102), a perforated reindeer tooth and bone needle production is present at Munzingen. Besides, at Munzingen two *bâtons percés*, three smoothers made out of massive bones, a chisel-like antler rod, a pointed antler rod with a large perforated hole at its massive base, an unfinished pendant made of jet, and two fragments of mammoth ivory are present. Last but not least, like at Munzingen, the fauna in some Lower Magdalenian sites is also dominated by reindeer (Ducasse et al., 2011, p. 127; Langlais et al., 2010, p. 35; Primault et al., 2007a, p. 15). However, this argument does not need to support a high age within the Magdalenian since dominance of reindeer may be a regional and not a chronological pattern (Kuntz and Costamagno, 2011, p. 14).

CONCLUSION

To conclude, Munzingen is a large Magdalenian site with distinctive lithic and organic artefacts that was excavated within a loess deposit. Since it was excavated a hundred years ago, no observations on fine stratigraphy are available and the correlation to the lithics of later salvage excavations cannot be easily assessed. However, when recent advances in research on the early part of the Magdalenian of France are taken into account, Munzingen can justifiably be assigned to the ca. 20–18 ka cal. BP old Lower Magdalenian on the basis of the reindeer antler points. This interpretation is supported by five of nine reliable radiocarbon dates, the presence of woolly rhinoceros and by the (aeolian?) loess cover. Characteristic lithic artefacts may support this attribution as well but, as always, their interpretation is not without ambiguity.

FINAL DISCUSSION

If Munzingen represents a 20–18 ka cal. BP old site, its geographic position at the eastern margin of the Lower Magdalenian landscape (Street et al., 2012, tabl. 1) has to be emphasized. Of course, demographic data are tentative but some estimations indicate ca. 7,000 individuals in France and Germany (Delpech, 1999, p. 36) or ca. 30,000 individuals in Europe (Bocquet-Appel et al., 2005). It is difficult to say which human lifeway is responsible for the presence of a distinct lithic and organic toolkit within a vast territory with a low population density and why this toolkit changed after some millennia. However, a glance on the late prehistoric and historic North American Arctic and Subarctic may widen our horizon of knowledge on hunter-gatherer lifeways in general: for example, the volcanic eruption around AD 900 along the Alaska-Yukon border may have been the cause of human emigration (e.g. Moodie and Catchpole, 1992) but also recent research has shown that this volcanic eruption separates two periods in the Southern Yukon, where hunting technology using throwing darts was abruptly replaced by bow and arrow, the preferred wood for projectile shafts shifted from birch to spruce, and the preferred armature for projectiles changed from stone to antler (Hare et al., 2012, p. 133). This may support the view that “environmental factors (...) are relevant for migration processes” (Widlok et al., 2012, p. 64). In contrast, it has to be emphasized that the history of some subarctic and arctic regions (see for example Csonka, 1995; Marshall, 1996; Pasda, 2014 or Sørensen, 2010) shows that it is much more complicated since “a complex mixture of rational and non-rational elements under a specific set of conditions” (Hill, 2013, p. 230) was responsible for cultural and technological changes often within one generation and with differences between neighbouring regions. These historic foragers had detailed information on landscape and humans on a continental scale as traded goods could traverse 1,600 km within a year (Hill, 2013, p. 95), linking “people in a region of some 300,000 km² into a single communication system” (Burch, 1975, p. 9) with vast networks of orally transmitted trails (Aporta, 2009 ; Burch, 2005, p. 215–219). Therefore, foragers were capable to cover enormous distances by foot within a short time period. For example, in spring 1771, a Chipewyan group walked more than 300 km in very rough country during 25 days (Burch, 1991, p. 443), in summer 1869, a group of Chipewyan, following the caribou migration, covered a distance of 500

km as the crow flies within 44 days, often in extremely difficult conditions (Burch, 1991, p. 443), or in 1854, a Gwich'in group walked around 2,400 km within five or six months as part of their ordinary annual movement (Hill, 2013, p. 7–8). Therefore, it is not surprising that, sometimes, these foragers changed their way of life with purpose. For example, in the 18th century a group of Athapaskan-speaking inland foragers travelled over the high-altitude glaciers of the St. Elias-Range to live at the Pacific coast to become complex Tlingit hunter-gatherers by adopting their language and customs (Cruikshank, 2005, p. 33–36). Another example is from Northwest Alaska where around 1880, a group of upper Kobuk Koyukon Indians voluntarily, without stress or crisis by war, famine, disease, or Western intrusion, decided to become Iñupiaq Eskimo (Hill, 2013, p. 127–146). When humans with a foraging lifeway of the historic past have not been driven by the environment but were active participants in the world, this may have been the case in prehistoric times as well. From this point of view, Munzingen is but one (Lower?) Magdalenian site in a 20–14.7 ka cal. BP old cultural landscape that connected the Upper Rhine plain with the Late Würmian mouth of the Rhône and the Pleistocene Bay of Biscay.

Acknowledgments: The author thanks the organizers of the SPF conference 2013 at Besançon for their invitation to write about Munzingen. The final version of this article was benefited of information provided by Claus-Joachim Kind (Esslingen, D) and of discussions with Michael Baales (Olpe, D), Denise Leesch (Neuchâtel, CH) and Werner Müller (Neuchâtel, CH). The comments of two anonymous reviewers were much appreciated. Photos and drawings in fig. 1–8 from Pasda (1994), final shaping of figures by Annett Schröter (Jena, D).

NOTES

- (1) August Padtberg was born in 1877 in Osnabrück (Germany) and died in Brazil in 1948 (Rabuske, 1981). In 1896 he became a Jesuit and lived in Brazil from 1903–07 where he became a Brazilian citizen. In 1912–17 Padtberg studied at the University of Freiburg and published articles on archaeology and evolution. In 1925, he left the Jesuit order and emigrated to Brazil where he became employed by the National Museum working as an archaeologist, e.g. at Lagoa Santa, but also as a teacher and university professor.
- (2) According to other scholars, reindeer was also present in later times (Béreiziat, 2013, p. 99; Drucker et al., 2011).
